

Copy to Whiteaves
Aug/81

The eye and part of
the Culicids. I am well
and of about age
now. I think I need
to send a few pupae
specimens - weathering
specimens. I hope I suspect
it is a kind of pest
crust shell. It is held
in form with about 3 tubules
and a large umbilicus. The
pupa is small and not very
microscopic. The
aperture is then expanded
circula with a slight angle
at the inner and outer
edge. There is means
here for insects. ~~A comparison~~
but that the small does
not. Will for many

When at Campbellton last
week I visited a very re-
markable place where I
discovered that the fossil
had discovered fossils,
in about several of
fossils seen in a
bed at the base
of the Devon beds
With the fossils are
several of plants. Fossils
plants are occasionally
with spores, alga
and also various
forms of a *Spirulina*
probably new. But
what must that be
was a *Spirulina* of

Compare the decay
sailing with the views
Ford has sent to you
and let me know
what you think.

I fear about the
shell can have been
warmed but have
but means of comparison
here with the Pulmonaria
& ~~the~~ Pulverinids

If you are desirous
to describe it, I shall
be glad to give you facts
as to its appearance &
mode of occurrence. All
what we want I fear
occurs and if you
have no specimens as
perfect as those of you

I can give you the
applying & securing
my specimens. There
are specimens which in
my view I can place
in more structure.

Please advise me
in view as I think
of the there is about 9
papers as I should desire
to examine the form of
the same.

This problem is
a most curious one. I col-
lected a large quantity
of specimens which will be
at your service when you
wish to check the paper
which I think highly valuable
for the of your own collection.
