Dear Sir

While in conversation with a person who sells Spectacles the other day he stated that the pebble glass was about  $10^{\circ}$  different in temperature - I have forgotten whether higher or lower - from ordinary glass. Is there any reason for stating that there is a real difference in the temperature of various minerals in the same case? I can understand how it can be apparent, <sup>to touch</sup> as one ~~is~~ maybe a better conductor than the other. If not trespassing

on your time may  
I ask a reply  
Yours respectfully  
L. M. England  
(arrs-'83).
